Abstract

Java Applet And Its Variety Of Application in Programming

Java is an object-oriented, multi - purpose, multi - platform language. This unique capability not only enables the user to organize the program code into logical units called objects, but also allow user to take advantage of encapsulation, inheritance, and polymorphism. In Java, there is variety of application for which programming can be done, that is, in J2ME (Java based mobile application/s), J2EE (Java application based server programming), J2SE (Java based software development), etc. Java program can be written, once-compiled, and run anywhere, that is, the same application program can be written in one OS (Windows) can be used on other OS (Linux). An applet is a program written in the Java programming language that can be included in an HTML page, much in the same way an image is included in a page. When a Java technology-enabled browser is used to view a page that contains an applet, the applet's code is transferred to the system and executed by the browser's Java Virtual Machine (JVM). For example, to include an applet in html page the <APPLET> tag is used, that is, <applet code = '____.____' archive = '_____.jar', width = ___, height = ___ /> where code is the name of the applet class, archive is the name of jar file containing the applet and its resources, width is the width of the applet and height is the height of the applet. In this paper, the various features of java applet related with application based programming are explored.
